More specifically, it relates to a process for the production of a poly(alkyl acrylate) polymer wherein a large quantity of oligomers are produced in an early portion of the polymerization. The oligomers are then converted to the desired polymer. One of the major disadvantages of free radical polymerization processes is that the free radical initiators themselves are very unstable and tend to decompose into very reactive species such as carbon monoxide and hydroperoxides. Although means exist to eliminate these species, they are to some extent unavoidable during the polymerization process. If the polymerization reaction proceeds to a stage wherein the temperature is high, these reactive species may react and/or degrade the polymer being formed and lead to a poor product.
